Abstract. We provide two equivalent approaches for computing the tail distribution of the first hitting time of the boundary of the Weyl chamber by a radial Dunkl process. The first approach is based on a spectral problem with initial value. The second one expresses the tail distribution by means of the W -invariant Dunkl–Hermite polynomials. Illustrative examples are given by the irreducible root systems of types A , B , D . The paper ends with an interest in the case of Brownian motions for which our formulae take determinantal forms.

Key words: radial Dunkl processes; Weyl chambers; hitting time; multivariate special functions; generalized Hermite polynomials

1 Motivation

The first exit time from cones by a multidimensional Brownian motion has been of great interest for mathematicians [2, 8] and for theoretical physicists as well [5]. An old and famous example of cones is provided by root systems in a finite dimensional Euclidean space, say $(V, \langle \cdot, \cdot \rangle)$ [15]. More precisely, a root system R in V is a collection of non zero vectors from V such that $\sigma_\alpha(R) = R$ for all $\alpha \in R$, where σ_α is the reflection with respect to the hyperplane orthogonal to α :

$$\sigma_\alpha(x) = x - 2 \frac{\langle \alpha, x \rangle}{\langle \alpha, \alpha \rangle} \alpha, \quad x \in V.$$

A simple system S is a basis of $\text{span}(R)$ which induces a total ordering in R . A root α is positive if it is a positive linear combination of elements of S . The set of positive roots is called a positive subsystem and is denoted by R_+ . The cone C associated with R , known as the positive Weyl chamber, is defined by

$$C := \{x \in V, \langle \alpha, x \rangle > 0 \forall \alpha \in R_+\} = \{x \in V, \langle \alpha, x \rangle > 0 \forall \alpha \in S\}.$$

For such cones, explicit formulae for the first exit time were given in [8] and involve Pfaffians of skew-symmetric matrices while [2] covers more general cones. During the last decade, a diffusion process valued in \overline{C} , the topological closure of C , was introduced and studied in a series of papers [4, 11, 12, 13, 14] and generalizes the reflected Brownian motion, that is, the absolute value of a real Brownian motion. This diffusion, known as the radial Dunkl process, is associated with a root system and depends on a set of positive parameters called a multiplicity function often denoted k . The latter is defined on the orbits of the action of the group generated by all the reflections σ_α , $\alpha \in R$, the reflection group, and is constant on each orbit. Let X denote a radial Dunkl process starting at $x \in C$ and define the first hitting time of ∂C by

$$T_0 := \inf\{t, X_t \in \partial C\}.$$

^{*}This paper is a contribution to the Special Issue on Dunkl Operators and Related Topics. The full collection is available at <http://www.emis.de/journals/SIGMA/DunklOperators.html>

Let $l : \alpha \in R \mapsto k(\alpha) - 1/2$ be the so called index function [4]. Then it was shown in [4] that $T_0 < \infty$ almost surely (hereafter a.s.) if $-1/2 \leq l(\alpha) < 0$ for at least one $\alpha \in R$, and $T_0 = \infty$ a.s. if $l(\alpha) \geq 0$ for all $\alpha \in R$. Moreover, the tail distribution of T_0 may be computed from the absolute-continuity relations derived in [4]. Two cases are distinguished

- $0 \leq l(\alpha) \leq 1/2$ for all $\alpha \in R$ with at least one α such that $0 < l(\alpha) \leq 1/2$: the radial Dunkl process with index $-l$ hits ∂C a.s.;
- $-1/2 \leq l(\alpha) < 0$ for at least one α and $l(\beta) \geq 0$ for at least one β : X itself hits ∂C a.s.

In the first case, we shall address the problem in its whole generality and specialize our results to the types A, B, D , while in the second case we shall restrict ourselves to the type B . One of the reasons is that the second case needs two values of the multiplicity function or equivalently two orbits. Another reason is that, after a suitable change of the index function, we are led to the first case, that is, to the case when both indices are positive.

After this panorama, we present another approach which is equivalent to the one used before and has the merit to express the tail distribution through the W -invariant parts of the so-called Dunkl–Hermite polynomials¹. The last part is concerned with determinantal formulae obtained for the first hitting time of ∂C by a multi-dimensional Brownian motion. These formulae have to be compared to the ones obtained in [8].

2 First approach

2.1 First case

Let us denote by \mathbb{P}_x^l the law of $(X_t)_{t \geq 0}$ starting from $x \in C$ and of index function l . Let \mathbb{E}_x^l be the corresponding expectation. Recall that [4, p. 38, Proposition 2.15c], if $l(\alpha) \geq 0$ for all $\alpha \in R_+$, then

$$\mathbb{P}_x^{-l}(T_0 > t) = \mathbb{E}_x^l \left[\left(\prod_{\alpha \in R_+} \frac{\langle \alpha, X_t \rangle}{\langle \alpha, x \rangle} \right)^{-2l(\alpha)} \right].$$

Recall that the semi group density of X is given by [4, 19]

$$p_t^k(x, y) = \frac{1}{c_k t^{\gamma+m/2}} e^{-(|x|^2+|y|^2)/2t} D_k^W \left(\frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) \omega_k^2(y), \quad x, y \in \bar{C},$$

where $\gamma = \sum_{\alpha \in R_+} k(\alpha)$ and $m = \dim V$ is the rank of R . The weight function ω_k is given by

$$\omega_k(y) = \prod_{\alpha \in R_+} \langle \alpha, y \rangle^{k(\alpha)}$$

and D_k^W is the generalized Bessel function. Thus,

$$\begin{aligned} \mathbb{P}_x^{-l}(T_0 > t) &= \prod_{\alpha \in R_+} \langle \alpha, x \rangle^{2l(\alpha)} \frac{e^{-|x|^2/2t}}{c_k t^{\gamma+m/2}} \int_C e^{-|y|^2/2t} D_k^W \left(\frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) \prod_{\alpha \in R_+} \langle \alpha, y \rangle dy \\ &= \prod_{\alpha \in R_+} \langle \alpha, \frac{x}{\sqrt{t}} \rangle^{2l(\alpha)} \frac{e^{-|x|^2/2t}}{c_k} \int_C e^{-|y|^2/2t} D_k^W \left(\frac{x}{\sqrt{t}}, y \right) \prod_{\alpha \in R_+} \langle \alpha, y \rangle dy \end{aligned}$$

¹They were called generalized Hermite polynomials in [20] but we prefer calling them as above to avoid the confusion with the generalized Hermite polynomials introduced by Lassalle [17].

$$= \prod_{\alpha \in R_+} \langle \alpha, \frac{x}{\sqrt{t}} \rangle^{2l(\alpha)} \frac{e^{-|x|^2/2t}}{c_k} g\left(\frac{x}{\sqrt{t}}\right),$$

where

$$g(x) := \int_C e^{-|y|^2/2} D_k^W(x, y) \prod_{\alpha \in R_+} \langle \alpha, y \rangle dy. \quad (1)$$

Our key result is stated as follows:

Theorem 1. *Let T_i be the i -th Dunkl derivative and $\Delta_k = \sum_{i=1}^m T_i^2$ the Dunkl Laplacian. Define*

$$\mathcal{J}_k^x := -\Delta_k^x + \sum_{i=1}^m x_i \partial_i^x := -\Delta_k^x + E_1^x,$$

where $E_1^x := \sum_{i=1}^m x_i \partial_i^x$ is the Euler operator and the superscript indicates the derivative action. Then

$$\mathcal{J}_k^x [e^{-|y|^2/2} D_k^W(x, y)] = E_1^y [e^{-|y|^2/2} D_k^W(x, y)].$$

Proof. Recall that if f is W -invariant then $T_i^x f = \partial_i^x f$ and that $T_i^x D_k(x, y) = y_i D_k(x, y)$ (see [20]). On the one hand [20]

$$\Delta_k^x D_k^W(x, y) = \sum_{i=1}^m y_i^2 \sum_{w \in W} D_k(x, wy) = |y|^2 D_k^W(x, y).$$

On the other hand,

$$\begin{aligned} E_1^x D_k^W(x, y) &= \sum_{w \in W} \sum_{i=1}^m x_i T_i^x D_k(x, wy) = \sum_{w \in W} \sum_{i=1}^m (x_i)(wy)_i D_k(x, wy) \\ &= \sum_{w \in W} \langle x, wy \rangle D_k(x, wy) = \sum_{w \in W} \langle w^{-1}x, y \rangle D_k(x, wy) \\ &= E_1^y D_k^W(x, y), \end{aligned}$$

where the last equality follows from $D_k(x, wy) = D_k(w^{-1}x, y)$ since $D_k(wx, wy) = D_k(x, y)$ for all $w \in W$. The result follows from an easy computation. \blacksquare

Remark 1. The appearance of the operator \mathcal{J}_k is not a mere coincidence and will be explained when presenting the second approach.

Corollary 1. g is an eigenfunction of $-\mathcal{J}_k$ corresponding to the eigenvalue $m + |R_+|$.

Proof. Theorem 1 and an integration by parts give

$$\begin{aligned} -\mathcal{J}_k^x g(x) &= -\int_C E_1^y [e^{-|y|^2/2} D_k^W(x, y)] \prod_{\alpha \in R_+} \langle \alpha, y \rangle dy \\ &= -\sum_{i=1}^m \int_C y_i \prod_{\alpha \in R_+} \langle \alpha, y \rangle \partial_i^y [e^{-|y|^2/2} D_k^W(x, y)] dy \\ &= \sum_{i=1}^m \int_C e^{-|y|^2/2} D_k^W(x, y) \partial_i \left[y_i \prod_{\alpha \in R_+} \langle \alpha, y \rangle \right] dy \end{aligned}$$

$$= \int_C e^{-|y|^2/2} D_k^W(x, y) \prod_{\alpha \in R_+} \langle \alpha, y \rangle \sum_{i=1}^m \left[1 + \sum_{\alpha \in R_+} \frac{\alpha_i y_i}{\langle \alpha, y \rangle} \right] dy.$$

The proof ends after summing over i . ■

Remark 2. The crucial advantage in our approach is that we do not need the explicit expression of D_k^W . Moreover, though D_k^W can be expressed through multivariate hypergeometric series [1, 6, 7], it cannot in general help to compute the function g .

2.1.1 The A-type

This root system is characterized by

$$\begin{aligned} R &= \{\pm(e_i - e_j), 1 \leq i < j \leq m\}, & R_+ &= \{e_i - e_j, 1 \leq i < j \leq m\}, \\ S &= \{e_i - e_{i+1}, 1 \leq i \leq m-1\}, & C &= \{y \in \mathbb{R}^m, y_1 > y_2 > \cdots > y_m\}. \end{aligned}$$

The reflection group W is the permutations group S_m and there is one orbit so that $k = k_1 > 0$ thereby $\gamma = k_1 m(m-1)/2$. Moreover, D_k^W is given by (see [1, p. 212–214])²

$$\frac{1}{|W|} D_k^W(x, y) = {}_0F_0^{(1/k_1)}(x, y).$$

Hence, letting $y \mapsto V(y)$ be the Vandermonde function, one writes:

$$\mathbb{P}_x^l(T_0 > t) = V\left(\frac{x}{\sqrt{t}}\right)^{2l_1} \frac{|W| e^{-|x|^2/2t}}{c_k} \int_C e^{-|y|^2/2} {}_0F_0^{(1/k_1)}\left(\frac{x}{\sqrt{t}}, y\right) V(y) dy,$$

where $l_1 = k_1 - 1/2$. Besides, \mathcal{J}_k acts on W -invariant functions as

$$-\mathcal{J}_k^x = D_0^x - E_1^x := \sum_{i=1}^m \partial_i^{2,x} + 2k_1 \sum_{i \neq j} \frac{1}{x_i - x_j} \partial_i^x - \sum_{i=1}^m x_i \partial_i^x.$$

Finally, since g is W -invariant, then

$$\begin{aligned} (D_0^x - E_1^x) g(x) &= m \frac{m+1}{2} g(x), \\ g(0) &= m! \int_C e^{-|y|^2/2} V(y) dy = \int_{\mathbb{R}^m} e^{-|y|^2/2} |V(y)| dy. \end{aligned}$$

In order to write down g , let us recall that the multivariate Gauss hypergeometric function ${}_2F_1^{(1/k_1)}(e, b, c, \cdot)$ (see [3] for the definition) is the unique symmetric eigenfunction that equals 1 at 0 of (see [3, p. 585])

$$\begin{aligned} &\sum_{i=1}^m z_i(1-z_i) \partial_i^{2,z} + 2k_1 \sum_{i \neq j} \frac{z_i(1-z_i)}{z_i - z_j} \partial_i^z \\ &+ \sum_{i=1}^m [c - k_1(m-1) - (e+b+1 - k_1(m-1)) z_i] \partial_i^z \end{aligned} \quad (2)$$

²Authors used another normalization so that there is factor $\sqrt{2}$ in both arguments. Moreover the Jack parameter denoted there by α is the inverse of k_1 .

associated with the eigenvalue meb . Letting $z = (1/2)(1 - x/\sqrt{b})$, that is $z_i = (1/2)(1 - x_i/\sqrt{b})$ for all $1 \leq i \leq m$ and $e = (m + 1)/2$,

$$c = k_1(m - 1) + \frac{1}{2}[e + b + 1 - k_1(m - 1)] = \frac{b}{2} + \frac{k_1}{2}(m - 1) + \frac{m + 3}{4},$$

then, the resulting function is an eigenfunction of

$$\sum_{i=1}^m \left(1 - \frac{x_i^2}{b}\right) \partial_i^{2,x} + 2k_1 \sum_{i \neq j} \frac{(1 - x_i^2/b)}{x_i - x_j} \partial_i^x - \sum_{i=1}^m \left(b + \frac{m + 3}{2} - k_1(m - 1)\right) \frac{x_i}{b} \partial_i^x$$

and $D_0^x - E_1^x$ is the limiting operator as b tends to infinity. Hence,

Proposition 1. For $1/2 < k_1 \leq 1$,

$$g(x) = g(0)C(m, k_1) \lim_{b \rightarrow \infty} {}_2F_1^{(1/k_1)} \left[\frac{m + 1}{2}, b, \frac{b}{2} + \frac{k_1}{2}(m - 1) + \frac{m + 3}{4}, \frac{1}{2} \left(1 - \frac{x}{\sqrt{b}}\right) \right],$$

where

$$C(m, k_1)^{-1} = \lim_{b \rightarrow \infty} {}_2F_1^{(1/k_1)} \left(\frac{m + 1}{2}, b, \frac{b}{2} + \frac{k_1}{2}(m - 1) + \frac{m + 3}{4}, \frac{1}{2} \right).$$

Remark 3. One cannot exchange the infinite sum and the limit operation. Indeed, expand the generalized Pochhammer symbol as (see [1, p. 191])

$$(a)_\tau = \prod_{i=1}^m (a - k_1(i - 1))_{\tau_i} = \prod_{i=1}^m \frac{\Gamma(a - k_1(i - 1) + \tau_i)}{\Gamma(a - k_1(i - 1))}$$

and use Stirling formula to see that each term in the above product is equivalent to

$$(a + k_1(m - 1) + \tau_i)^{\tau_i}$$

for large enough positive a . Moreover, since $J_\tau^{(1/k_1)}$ is homogeneous, one has

$$J_\tau^{(1/k_1)} \left[\frac{1}{2} \left(1 - \frac{x}{\sqrt{b}}\right) \right] = 2^{-p} J_\tau^{(1/k_1)} \left(1 - \frac{x}{\sqrt{b}}\right), \quad |\tau| = p.$$

It follows that

$$\frac{(b)_\tau}{(b/2 + (m - 1)k_1/2 + (m + 3)/4)_\tau} J_\tau^{(1/k_1)} \left[\frac{1}{2} \left(1 - \frac{x}{\sqrt{b}}\right) \right] \approx J_\tau^{(1/k_1)}(1)$$

for large positive b . Thus, the above Gauss hypergeometric function reduces to

$${}_1F_0^{(1/k_1)} \left(\frac{m + 1}{2}, 1 \right).$$

Unfortunately, the above series diverges since [1]

$${}_1F_0^{(1/k_1)}(a, x) = \prod_{i=1}^m (1 - x_i)^{-a}.$$

2.2 The B -type

For this root system, one has

$$\begin{aligned} R &= \{\pm e_i, \pm e_i \pm e_j, 1 \leq i < j \leq m\}, & R_+ &= \{e_i, 1 \leq i \leq m, e_i \pm e_j, 1 \leq i < j \leq m\}, \\ S &= \{e_i - e_{i+1}, 1 \leq i \leq m, e_m\}, & C &= \{y \in \mathbb{R}^m, y_1 > y_2 > \cdots > y_m > 0\}. \end{aligned}$$

The Weyl group is generated by transpositions and sign changes ($x_i \mapsto -x_i$) and there are two orbits so that $k = (k_0, k_1)$ thereby $\gamma = mk_0 + m(m-1)k_1$ (we assign k_0 to $\{\pm e_i, 1 \leq i \leq m\}$). The generalized Bessel function³ is given by [1, p. 214]

$$\frac{1}{|W|} D_k^W(x, y) = {}_0F_1^{(1/k_1)} \left(k_0 + (m-1)k_1 + \frac{1}{2}, \frac{x^2}{2}, \frac{y^2}{2} \right),$$

where $x^2 = (x_1^2, \dots, x_m^2)$. Thus

$$g(x) = |W| \int_C e^{-|y|^2/2} {}_0F_1^{(1/k_1)} \left(k_0 + (m-1)k_1 + \frac{1}{2}, \frac{x^2}{2}, \frac{y^2}{2} \right) \prod_{i=1}^m (y_i) V(y^2) dy.$$

The eigenoperator \mathcal{J}_k acts on W -invariant functions as

$$-\mathcal{J}_k^x = \sum_{i=1}^m \partial_i^{2,x} + 2k_0 \sum_{i=1}^m \frac{1}{x_i} \partial_i^x + 2k_1 \sum_{i \neq j} \left[\frac{1}{x_i - x_j} + \frac{1}{x_i + x_j} \right] \partial_i^x - E_1^x,$$

therefore g solves the spectral problem with initial value

$$-\mathcal{J}_k^x g(x) = m(m+1)g(x), \quad g(0) = \int_{\mathbb{R}^m} e^{-|y|^2} \prod_{i=1}^m |y_i| |V(y^2)| dy.$$

A change of variable $x_i = \sqrt{2y_i}$ shows that $y \mapsto u(y) := g(\sqrt{2y})$ satisfies

$$\begin{aligned} -\tilde{\mathcal{J}}_k^y u(y) &= m \frac{(m+1)}{2} u(y), & u(0) &= g(0), \\ -\tilde{\mathcal{J}}_k^y &= \sum_{i=1}^m y_i \partial_i^{2,y} + 2k_1 \sum_{i \neq j} \frac{y_i}{y_i - y_j} \partial_i^y + \left(k_0 + \frac{1}{2} \right) \sum_{i=1}^m \partial_i^y - E_1^y. \end{aligned}$$

As a result,

$$u(y) = u(0) {}_1F_1^{(1/k_1)} \left(\frac{m+1}{2}, k_0 + (m-1)k_1 + \frac{1}{2}, y \right),$$

where

$${}_1F_1^{(1/k_1)}(b, c, z) = \sum_{p=0}^{\infty} \sum_{\tau} \frac{(b)_{\tau}}{(c)_{\tau}} \frac{J_{\tau}^{(1/k_1)}(z)}{p!}.$$

This can be seen from the differential equation (2) and using [1]

$$\lim_{e \rightarrow \infty} {}_2F_1^{(1/k_1)} \left(e, b, c, \frac{z}{e} \right) = {}_1F_1^{(1/k_1)}(b, c, z).$$

Finally

$$g \left(\frac{x}{\sqrt{t}} \right) = g(0) {}_1F_1^{(1/k_1)} \left(\frac{m+1}{2}, k_0 + (m-1)k_1 + \frac{1}{2}, \frac{x^2}{2t} \right)$$

and the tail distribution is given by:

³There is an erroneous sign in one of the arguments in [1]. Moreover, to recover this expression in the B_m case from that given in [1], one should make the substitutions $a = k_0 - 1/2$, $k_1 = 1/\alpha$, $q = 1 + (m-1)k_1$.

Proposition 2. For $1/2 \leq k_0, k_1 \leq 1$ with either $k_0 > 1/2$ or $k_1 > 1/2$, one has

$$\begin{aligned} \mathbb{P}_x^{-l}(T_0 > t) &= C_k \prod_{i=1}^m \left(\frac{x_i^2}{2t} \right)^{l_0} \left(V \left(\frac{x^2}{2t} \right) \right)^{2l_1} \\ &\quad \times e^{-|x|^2/2t} {}_1F_1^{(1/k_1)} \left(\frac{m+1}{2}, k_0 + (m-1)k_1 + \frac{1}{2}, \frac{x^2}{2t} \right), \end{aligned}$$

where $l_0 := k_0 - 1/2$, $l_1 := k_1 - 1/2$ and V stands for the Vandermonde function.

2.3 The D_m -type

This root system is defined by [15, p. 42]

$$R = \{\pm e_i \pm e_j, 1 \leq i < j \leq m\}, \quad R_+ = \{e_i \pm e_j, 1 \leq i < j \leq m\},$$

and there is one orbit so that $k(\alpha) = k_1$ thereby $\gamma = m(m-1)k_1$. The Weyl chamber is given by

$$C = \{x \in \mathbb{R}^m, x_1 > x_2 > \cdots > |x_m|\} = C_1 \cup s_m C_1,$$

where C_1 is the Weyl chamber of type B and s_m stands for the reflection with respect to the vector e_m acting by sign change on the variable x_m .

Proposition 3. For $1/2 < k_1 \leq 1$, the tail distribution writes

$$\mathbb{P}_x^{-l}(T_0 > t) = C_k \left[V \left(\frac{x^2}{2t} \right) \right]^{2l} e^{-|x|^2/2t} {}_1F_1^{(1/k_1)} \left(\frac{m}{2}, (m-1)k_1 + \frac{1}{2}, \frac{x^2}{2t} \right).$$

Proof. It nearly follows the one given for the root system of type B subject to the following modifications: if $x \in C_1$, then we perform the change of variable $x_i = \sqrt{2y_i}$, $1 \leq i \leq m$ and for $x \in s_m C_1$ we perform the change of variable $x_i = \sqrt{2y_i}$, $1 \leq i \leq m-1$ and $x_m = -\sqrt{2y_m}$. In both cases, one gets that $y \mapsto u(y) = g(x^2/2)$ is a symmetric eigenfunction of

$$\sum_{i=1}^m y_i \partial_i^{2,y} + 2k_1 \sum_{i \neq j} \frac{y_i}{y_i - y_j} \partial_i^y + \frac{1}{2} \sum_{i=1}^m \partial_i^y - \sum_{i=1}^m y_i \partial_i^y \quad (3)$$

corresponding to the eigenvalue $m^2/2$. This spectral problem with initial value 1 at $y = 0$ has a unique solution given by

$${}_1F_1^{(1/k_1)}(m/2, (m-1)k_1 + 1/2, y),$$

and the expression of the tail distribution follows. ■

2.4 Second formula

Suppose that $-1/2 \leq l(\alpha) < 0$ for at least one $\alpha \in R$ and $l(\beta) \geq 0$ for at least one $\beta \in R_+$. Then, by [4, Proposition 2.15b] one writes

$$\mathbb{P}_x^l(T_0 > t) = \mathbb{E}_x^0 \left[\prod_{\alpha \in R_+} \left(\frac{\langle \alpha, X_t \rangle}{\langle \alpha, x \rangle} \right)^{l(\alpha)} \exp \left(-\frac{1}{2} \sum_{\alpha, \zeta \in R_+} \int_0^t \frac{\langle \alpha, \gamma \rangle l(\alpha) l(\zeta)}{\langle \alpha, X_s \rangle \langle \zeta, X_s \rangle} ds \right) \right].$$

Using [4, Proposition 2.15a] it follows that

$$\mathbb{P}_x^l(T_0 > t) = \mathbb{E}_x^r \left[\prod_{\alpha \in R_+} \left(\frac{\langle \alpha, X_t \rangle}{\langle \alpha, x \rangle} \right)^{l(\alpha) - r(\alpha)} \exp \left(-\frac{1}{2} \sum_{\alpha, \zeta \in R_+} \int_0^t \frac{\langle \alpha, \zeta \rangle l(\alpha, \zeta)}{\langle \alpha, X_s \rangle \langle \zeta, X_s \rangle} ds \right) \right],$$

where $l(\alpha, \zeta) := l(\alpha)l(\zeta) - r(\alpha)r(\zeta)$ and

$$r(\alpha) = \begin{cases} l(\alpha) & \text{if } l(\alpha) \geq 0, \\ -l(\alpha) & \text{if } l(\alpha) < 0. \end{cases}$$

Then $l(\alpha, \zeta) = 0$ if $l(\alpha)l(\zeta) \geq 0$ and $l(\alpha, \zeta) = -2r(\alpha)r(\zeta)$ otherwise. As a result,

$$\mathbb{P}_x^l(T_0 > t) = \mathbb{E}_x^r \left[\prod_{\substack{\alpha \in R_+ \\ l(\alpha) < 0}} \left(\frac{\langle \alpha, x \rangle}{\langle \alpha, X_t \rangle} \right)^{2r(\alpha)} \exp \left(\sum_{\substack{\alpha, \zeta \in R_+ \\ l(\alpha)l(\zeta) < 0}} \int_0^t \frac{\langle \alpha, \zeta \rangle r(\alpha)r(\zeta)}{\langle \alpha, X_s \rangle \langle \zeta, X_s \rangle} ds \right) \right].$$

Next, note that the exponential functional in the RHS equals 1 for the irreducible root systems having only one orbit since the sum is empty. Fortunately, this is true for the type B . In fact, note that $l(\alpha)l(\zeta) < 0$ implies that α and ζ belong to different orbits. Thus, writing $R_+ = \{e_i, 1 \leq i \leq m\} \cup \{e_j \pm e_k, 1 \leq j < k \leq m\}$ so that $\langle e_i, e_j \pm e_k \rangle = \delta_{ij} \pm \delta_{ik}$ gives

$$\begin{aligned} S &= \sum_{i=1}^m \sum_{i < k} \frac{1}{X_t^i} \left[\frac{1}{X_t^i - X_t^k} + \frac{1}{X_t^i + X_t^k} \right] + \sum_{i=1}^m \sum_{k < i} \frac{1}{X_t^i} \left[\frac{-1}{X_t^k - X_t^i} + \frac{1}{X_t^k + X_t^i} \right] \\ &= \sum_{i=1}^m \sum_{i < k} \frac{2}{(X_t^i)^2 - (X_t^k)^2} - \sum_{i=1}^m \sum_{k < i} \frac{2}{(X_t^k)^2 - (X_t^i)^2} = 0, \end{aligned}$$

where S stands for the sum in the above exponential functional (up to a constant). Hence,

$$\begin{aligned} \mathbb{P}_x^l(T_0 > t) &= \mathbb{E}_x^r \left[\prod_{\substack{\alpha \in R_+ \\ l(\alpha) < 0}} \left(\frac{\langle \alpha, x \rangle}{\langle \alpha, X_t \rangle} \right)^{2r(\alpha)} \right] = \frac{1}{c_k t^{\gamma + m/2}} \prod_{\substack{\alpha \in R_+ \\ l(\alpha) < 0}} \langle \alpha, x \rangle^{-2l(\alpha)} e^{-|x|^2/2t} \\ &\quad \times \int_C e^{-|y|^2/2t} D_k^W \left(\frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) \prod_{\substack{\alpha \in R_+ \\ l(\alpha) \geq 0}} \langle \alpha, y \rangle^{2l(\alpha)+1} \prod_{\substack{\alpha \in R_+ \\ l(\alpha) < 0}} \langle \alpha, y \rangle dy. \end{aligned}$$

For instance, when $k_0 < 1/2$, $k_1 \geq 1/2$ for which $-1/2 \leq l_0 < 0$, $l_1 \geq 0$, the last integral reads:

$$f(x) := \int_C e^{-|y|^2/2t} D_k^W(x, y) V(y^2)^{2l_1+1} \prod_{i=1}^m y_i dy$$

while for $k_0 \geq 1/2$, $0 < k_1 < 1/2$, it reads

$$f(x) := \int_C e^{-|y|^2/2t} D_k^W(x, y) V(y^2) \prod_{i=1}^m y_i^{2l_0} dy.$$

Theorem 1 still applies and its corollary needs minor modifications when integrating by parts. The interested reader can easily see that f is an eigenfunction of $-\mathcal{J}_k$ corresponding to the eigenvalue

$$m + \sum_{\substack{\alpha \in R_+ \\ l(\alpha) \geq 0}} [2l(\alpha) + 1] + \sum_{\substack{\alpha \in R_+ \\ l(\alpha) < 0}} 1 = m + |R_+| + 2 \sum_{\substack{\alpha \in R_+ \\ l(\alpha) \geq 0}} l(\alpha).$$

3 Tail distribution of T_0 and W -invariant Dunkl–Hermite polynomials

In the sequel, we give an insight to the appearance of the eigenoperator \mathcal{J}_k in our previous computations and show that it is not a mere coincidence. Indeed, this operator already appeared in [20] and is related to the W -invariant counterparts of the so called Dunkl–Hermite polynomials. This fact was behind our attempt to develop an equivalent approach to the previous one for which the index function is positive. We will give another proof of Theorem 1 then express $e^{-|x|^2/2}g(x)$ by means of the W -invariant Dunkl–Hermite polynomials. To proceed, we recall some needed facts.

3.1 Dunkl–Hermite polynomials

These polynomials are defined by (see [20] where they were called generalized Hermite polynomials)

$$H_\tau := e^{-\Delta_k/2} \phi_\tau, \quad \tau = (\tau_1, \dots, \tau_m) \in \mathbb{N}^m,$$

where $(\phi_\tau)_{\tau \in \mathbb{N}^m}$ are homogeneous polynomials of degree $|\tau| = \tau_1 + \dots + \tau_m$ and form an orthogonal basis of the vector space of polynomials with real coefficients with respect to the pairing inner product introduced in [10]

$$[p, q]_k = \int_V e^{-\Delta_k/2} p(x) e^{-\Delta_k/2} q(x) \omega_k^2(x) dx$$

for two polynomials p, q (up to a constant factor). $(H_\tau)_\tau$ are then said to be associated with the basis $(\phi_\tau)_\tau$. By analogy to the one dimensional classical Hermite polynomials, we recall the generating series, the spectral problem and the Mehler-type formula [9, 20]

$$e^{-|y|^2/2} D_k(x, y) = \sum_{\tau} H_\tau(x) \phi_\tau(y), \quad (4)$$

$$-\mathcal{J}_k = [\Delta_k - \langle x, \nabla \rangle] H_\tau(x) = -|\tau| H_\tau(x), \quad (5)$$

$$\sum_{\tau \in \mathbb{N}^m} H_\tau(x) H_\tau(y) r^{|\tau|} = \frac{1}{(1-r^2)^{\gamma+m/2}} \exp\left(-\frac{r^2(|x|^2 + |y|^2)}{2(1-r^2)}\right) D_k\left(x, \frac{r}{1-r^2} y\right), \quad (6)$$

for $0 < r < 1$.

3.2 W -invariant Dunkl–Hermite polynomials

They are defined up to a constant by

$$H_\tau(x) := \sum_{w \in W} H_\tau(wx)$$

and analogs of (4), (5), (6) exist and are derived as follows. Summing twice over W in (4) and using $D_k(wx, w'y) = D_k(x, w^{-1}w'y)$, $w, w' \in W$ [20] give

$$\sum_{w, w' \in W} e^{-|y|^2/2} D_k(wx, w'y) = |W| e^{-|y|^2/2} D_k^W(x, y) = \sum_{\tau} H_\tau^W(x) \sum_{w \in W} \phi_\tau(wy)$$

or equivalently

$$e^{-|y|^2/2} D_k^W(x, y) = \sum_{\tau} H_\tau^W(x) \phi_\tau^W(y), \quad \phi_\tau^W(y) := \frac{1}{|W|} \sum_{w \in W} \phi_\tau(wy). \quad (7)$$

Similarly, (6) transforms to

$$\sum_{\tau \in \mathbb{N}^m} H_\tau^W(x) H_\tau^W(y) r^{|\tau|} = \frac{|W|}{(1-r^2)^{\gamma+m/2}} \exp -\frac{r^2(|x|^2 + |y|^2)}{2(1-r^2)} D_k^W \left(x, \frac{r}{1-r^2} y \right). \quad (8)$$

Finally, summing once over W in (5) and using the fact that Δ_k and $\langle x, \nabla \rangle$ commute with the action of W (or are W -invariant, see [9, p. 169]), one gets

$$[\Delta_k - \langle x, \nabla \rangle] H_\tau^W(x) = -|\tau| H_\tau^W(x). \quad (9)$$

3.3 Second approach

After this wave of formulae, Theorem (1) easily follows after applying (9) to (7) and using the homogeneity of ϕ_τ^W . Moreover, we derive the following expansion

Proposition 4. *Let g be the function defined by (1), then*

$$e^{-|x|^2/2} g(x) = \frac{1}{|W| 2^{\gamma+m/2}} \sum_{\tau \in \mathbb{N}^m} c_\tau^W H_\tau^W(x),$$

where

$$c_\tau^W = \frac{1}{2^{|\tau|/2}} \int_C e^{-|y|^2/2} H_\tau^W(y) \prod_{\alpha \in R_+} \langle \alpha, y \rangle dy.$$

Proof. Substituting D_k^W in (1) and using the variable change $y \mapsto ry/(1-r^2)$ yield (since C is a cone)

$$\begin{aligned} g(x) &= C_{k,r} e^{r^2|x|^2/(2(1-r^2))} \sum_{\tau \in \mathbb{N}^m} H_\tau^W(x) r^{|\tau|} \int_C e^{-|ry|^2/2} H_\tau^W \left(\frac{1-r^2}{r} y \right) \prod_{\alpha \in R_+} \langle \alpha, y \rangle dy \\ &= C_{k,r} e^{r^2|x|^2/(2(1-r^2))} \sum_{\tau \in \mathbb{N}^m} H_\tau^W(x) r^{|\tau|} \int_C e^{-|y|^2/2} H_\tau^W \left(\frac{1-r^2}{r^2} y \right) \prod_{\alpha \in R_+} \langle \alpha, y \rangle dy \end{aligned}$$

for some constants $C_{k,r}$ depending on k, r . The result follows by choosing $r = 1/\sqrt{2}$. \blacksquare

Finally, in order to derive c_τ^W , one needs

Proposition 5 (an integration by part formula). *Let $(T_i)_{i=1}^m$ be the Dunkl derivatives [20]. Then, c_τ^W are given by*

$$c_\tau^W = (-1)^{|\tau|} \int_C \phi_\tau^W(T_1, \dots, T_m) (e^{-|y|^2/2}) \prod_{\alpha \in R_+} \langle \alpha, y \rangle dy.$$

Remark 4. By Heckman's result (see paragraph at the end of p. 169 in [9]), $\phi_\tau^W(T_1, \dots, T_m)$ acts on $y \mapsto e^{-|y|^2/2}$ as a differential operator so that one may perform an integration by parts on the above integral.

Proof. Recall the Rodriguez-type formula for H_τ [20]

$$H_\tau(y) = (-1)^{|\tau|} e^{|y|^2/2} \phi_\tau(T_1, \dots, T_m) (e^{-|y|^2/2}).$$

The equivariance of the Dunkl operators (see [9, p. 169]) yields

$$H_\tau(\omega y) = (-1)^{|\tau|} e^{|y|^2/2} \phi_\tau(\omega^{-1} \cdot)(T_1, \dots, T_m) (e^{-|y|^2/2})$$

so that, after summing over W , one gets

$$H_\tau^W(y) = (-1)^{|\tau|} e^{|y|^2/2} \phi_\tau^W(T_1, \dots, T_m) (e^{-|y|^2/2})$$

which ends the proof. \blacksquare

4 Examples

4.1 B -type root systems

From results in [1, p. 213], one has on the one hand

$$H_{2\tau}^W(x) = L_\tau^a(x^2/2), \quad a = k_0 - 1/2 = l_0$$

and 0 otherwise, where L_τ^a is the generalized Laguerre polynomial defined in [16] and τ in the RHS may be seen as a partition of length m since H_τ^W is symmetric (we omitted the dependence on the Jack parameter $1/k_1$ for sake of clarity, see [1] for the details). On the other hand, recall that when $1/2 \leq k_0, k_1 \leq 1$ with either $k_0 > 1/2$ or $k_1 > 1/2$, we derived

$$\begin{aligned} e^{-|x|^2/2}g(x) &= e^{-|x|^2/2} {}_1F_1^{(1/k_1)}\left(\frac{m+1}{2}, k_0 + (m-1)k_1 + \frac{1}{2}, \frac{x^2}{2}\right) \\ &= {}_1F_1^{(1/k_1)}\left(k_0 - k_1 + m(k_1 - 1/2), k_0 + (m-1)k_1 + \frac{1}{2}, -\frac{x^2}{2}\right) \end{aligned}$$

by Kummer's relation

$$e^{-(x_1 + \dots + x_m)} {}_1F_1^{(1/k_1)}(a, b, x) = {}_1F_1^{(1/k_1)}(b - a, b, -x)$$

whenever it makes sense. Using [1, Proposition 4.2] with $z = (1/2, \dots, 1/2)$, $a = k_0 - 1/2$, $q = 1 + (m-1)k_1$, $\alpha = 1/k_1$, one gets

$$\begin{aligned} e^{-|x|^2/2}g(x) &= \frac{1}{2^{(m+1)/2}} \sum_\tau \frac{[(l_0 - l_1) + ml_1]_\tau}{[k_0 + (m-1)k_1 + 1/2]_\tau} J_\tau^{(1/k_1)}\left(\frac{1}{2}\right) L_\tau^{k_0-1/2}\left(\frac{x^2}{2}\right) \\ &= \sum_\tau \frac{[(l_0 - l_1) + ml_1]_\tau}{[k_0 + (m-1)k_1 + 1/2]_\tau} \frac{1}{2^{(m+1)/2+|\tau|}} J_\tau^{(1/k_1)}(1) L_\tau^{k_0-1/2}\left(\frac{x^2}{2}\right), \end{aligned}$$

where $l_i = k_i - 1/2$, $i = 1, 2$. Here $J_\tau^{(1/k_1)}$ is the normalized Jack polynomial denoted $C_\tau^{(\alpha)}$ in [1] and is related to ϕ_τ^W as [1, p. 201]

$$\phi_\tau^W(y) = \frac{(-1)^{|\tau|} J_\tau^{(1/k_1)}(y^2)}{|\tau|! J_\tau^{(1/k_1)}(1)}.$$

Comparing the coefficients in the expansion of $x \mapsto e^{-|x|^2/2}g(x)$, one gets

$$\int_C J_\tau^{1/k_1}(T_1^2, \dots, T_m^2) (e^{-|y|^2/2}) V(y^2) \prod_{i=1}^m y_i dy = \frac{[(k_0 - k_1) + m(k_1 - 1/2)]_\tau}{[k_0 + (m-1)k_1 + 1/2]_\tau} \frac{|\tau|! [J_\tau^{(1/k_1)}(1)]^2}{2^{(m+1+|\tau|)/2}},$$

where $C = \{x_1 > \dots > x_m > 0\}$.

4.2 D -type root systems

Similarly, one has

$$\begin{aligned} e^{-|x|^2/2}g(x) &= e^{-|x|^2/2} {}_1F_1^{(1/k_1)}\left(m/2, (m-1)k_1 + 1/2, \frac{x^2}{2}\right) \\ &= {}_1F_1^{(1/k_1)}\left((m-1)l_1, (m-1)k_1 + 1/2, -\frac{x^2}{2}\right) \\ &= \sum_\tau \frac{[(m-1)l_1]_\tau}{[(m-1)k_1 + 1/2]_\tau} L_\tau^{-1/2}\left(\frac{x^2}{2}\right) \frac{J_\tau^{(1/k_1)}(1)}{2^{m/2+|\tau|}}. \end{aligned}$$

4.3 A-type root systems

We have already seen that, for $k_1 > 1/2$, g is expressed as a limit of a Gauss multivariate series. With the second approach in hand, g may be expanded by means of the generalized Hermite polynomials defined in [17] and denoted H_τ there, where τ is a partition of length m (see [1] for details). In particular, this fact may be seen for the value $k = 1/2$ as follows, though it has no probabilistic interpretation since X does not hit ∂C . Indeed, one seeks an eigenfunction g of

$$\sum_{i=1}^m \partial_i^2 + \sum_{i \neq j} \frac{1}{x_i - x_j} \partial_i - \sum_{i=1}^m x_i \partial_i, \quad x \in C,$$

associated with the eigenvalue $m + |R_+| = m + m(m-1)/2$ and such that $g(0) = 1$. Easy computations using

$$\sum_{i \neq j} \frac{x_i}{x_i - x_j} = \frac{m(m-1)}{2}$$

shows that $g(x) = e^{|x|^2/2}$. Using [1, Proposition 3.1] with $z = (1/\sqrt{2}, \dots, 1/\sqrt{2})$ ⁴, one gets

$$\begin{aligned} e^{|x|^2/2} &= {}_0F_0^{(2)}(x^2/2) = e^{1/2} \sum_{\tau} \frac{1}{|\tau|!} H_{\tau}(x^2/2) J_{\tau}^{(1/k_1)}(1/\sqrt{2}) \\ &= e^{1/2} \sum_{\tau} \frac{1}{2^{|\tau|/2} |\tau|!} H_{\tau}(x^2/2) J_{\tau}^{(1/k_1)}(1). \end{aligned}$$

For general $1/2 < k \leq 1$, one may use the fact that ϕ_{τ}^W is (up to a constant) is a Jack polynomial $J_{\tau}^{(1/k_1)}$ [1, p. 190] so that

$$c_{\tau}^W = (-1)^{\tau} \int_{x_1 > \dots > x_m} J_{\tau}^{(1/k_1)}(T_1, \dots, T_m) (e^{-|y|^2/2}) V(y) dy$$

where τ is a partition of length m .

5 Remarks on the first exit times of Brownian motions from C

In [8], authors used a combinatorial approach to write down the tail distribution of the first exit time from the Weyl chamber of a given root system R by a m -dimensional Brownian motion starting at $x \in C$. The result is valid for a wider class of homogeneous W -invariant Markov processes and the tail distribution was expressed as Pfaffians of skew symmetric matrices [21]. While we can show, via the heat equation

$$\frac{1}{2} \Delta u(x, t) = \partial_t u(x, t), \quad u(x, t) = \mathbb{P}_x^l(T_0 > t),$$

with appropriate boundary values, that our results agree with the ones in [8], we do not succeed to come from Pfaffians to determinants and vice versa. Nevertheless, we do have the following remark: on the one hand, since the m -dimensional Brownian motion corresponds to a radial Dunkl process with a null multiplicity function or index function $-l \equiv -1/2$, then our first approach applies with $k = 1$ so that the Jack parameter $(1/k_1)$ equals one. In this case, it is known

⁴We use a rescaling of the generalized Hermite polynomials so that they are orthogonal with respect to $V(x)^{2k} e^{-|x|^2/2}$ rather than $V(x)^{2k} e^{-|x|^2}$, where V is the Vandermonde function.

that multivariate hypergeometric series of one argument have determinantal representations. For instance, for both B and D -types, our formula derived in Subsection 2.1 specialize to

$$\mathbb{P}_x^{-1/2}(T_0 > t) = C \det \left[\left(\frac{x_i^2}{2t} \right)^{m-j+1/2} {}_1\mathcal{F}_1 \left(\frac{m}{2}, m-j+\frac{3}{2}, -\frac{x_i^2}{2t} \right) \right]_{i,j=1}^m,$$

$$\mathbb{P}_x^{-1/2}(T_0 > t) = C \det \left[\left(\frac{x_i^2}{2t} \right)^{m-j} {}_1\mathcal{F}_1 \left(\frac{m-1}{2}, m-j+\frac{1}{2}, -\frac{x_i^2}{2t} \right) \right]_{i,j=1}^m$$

for both the B and D -types root systems respectively, where ${}_1\mathcal{F}_1$ is the confluent hypergeometric function. On the other hand, in that cases and for even integers m , one has [8]

$$\mathbb{P}_x^{-1/2}(T_0 > t) = Pf \left(\gamma[(x_i - x_j)/\sqrt{2t}] \gamma[(x_j)/\sqrt{t}] \right)_{1 \leq i, j, \leq m},$$

$$\mathbb{P}_x^{-1/2}(T_0 > t) = Pf \left(\gamma[(x_i - x_j)/\sqrt{2t}] \gamma[(x_i + x_j)/\sqrt{2t}] \right)_{1 \leq i, j, \leq m},$$

where

$$\gamma(a) = \sqrt{\frac{2}{\pi}} \int_0^a e^{-z^2/2} dz,$$

which may be expressed as [18]

$$\gamma(a) := \frac{a}{\sqrt{2\pi}} {}_1\mathcal{F}_1(1/2, 3/2; -a^2/2).$$

Now, recall that (see [21, Proposition 2.3])

$$Pf[\lambda_i \lambda_j]_{1 \leq i < j \leq m} = \prod_{i=1}^m \lambda_i, \tag{10}$$

where in the LHS, the entries of the skew symmetric matrix are $a_{ij} = -a_{ji} = \lambda_i \lambda_j$ for $i < j$. As a result, if $(\lambda_i)_{1 \leq i \leq m}$ are thought of as eigenvalues of some matrix, this formula relates Pfaffians to determinants and we think that it is the way to come from Pfaffians to determinants at least in these cases. We do not have a proof since on the one hand, it is not easy to write down the above determinants as a product of eigenvalues and on the other hand, we are not able to separate the variables x_i and x_j as stated in (10).

Acknowledgements

The author would like to thank C. Donati Martin for useful remarks and her careful reading of the paper, and P. Bougerol for explanations of some facts on root systems. He is grateful to M. Yor for his intensive reading of the manuscript and encouragements.
